In each case, write a balanced equation for the combustion of the given compound. Assume complete combustion.

1. heptane, $\mathrm{C}_{7} \mathrm{H}_{16}$
2. 2,2-dimethylbutane
3. 1,1,3-trimethylcyclohexane
4. 2-heptanol, $\mathrm{C}_{7} \mathrm{H}_{16} \mathrm{O}$
5. 1,6-hexanediol, $\mathrm{C}_{6} \mathrm{H}_{14} \mathrm{O}_{2}$

Answers

1. $\mathrm{C}_{7} \mathrm{H}_{16}(\mathrm{l})+11 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 7 \mathrm{CO}_{2}(\mathrm{~g})+8 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$

This equation shows the essential features. Ordinary complete combustion refers to the complete oxidation by $\mathrm{O}_{2}$, producing the major oxides. For compounds of C and H (and O ) those are $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$. That is, the general reaction is

$$
<\text { compound of } \mathrm{CHO}>+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

You should think about the phases. You may or may not know the phase of the organic reactant, but I bet you "know" more of them than you think; give them a try. It's reasonable to show the phase of water as either gas or liquid. It is a gas under the conditions of the combustion, but can be thought of as a liquid, back at "standard conditions".

As to balancing, there is a basic approach which generally works well for any CHO compound. Start with the organic compound. There is enough C to make how many $\mathrm{CO}_{2}$ ? There is enough H for how many $\mathrm{H}_{2} \mathrm{O}$ ? Now, calculate how many O are on the right, and provide them on the left.
2. First, you need to figure out what the chemical is, from the name. You should be able to draw it. But all we need for balancing is the molecular formula. It has $\mathrm{C}_{6}$. It is an alkane, so has $\mathrm{H}_{2 \mathrm{~N}+2}=\mathrm{H}_{14}$ in this case. Thus the molecular formula is $\mathrm{C}_{6} \mathrm{H}_{14}$. Now, you write and balance the combustion equation as above: $\mathrm{C}_{6} \mathrm{H}_{14}(\mathrm{l})+19 / 2 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 6 \mathrm{CO}_{2}(\mathrm{~g})+7 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$
3. The compound is $\mathrm{C}_{9} \mathrm{H}_{18}$. Note that it has one ring, thus is short 2 H from having the $2 \mathrm{~N}+2$ maximum number of $\mathrm{H} . \quad \mathrm{C}_{9} \mathrm{H}_{18}(\mathrm{l})+27 / 2 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 9 \mathrm{CO}_{2}(\mathrm{~g})+9 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$
4. This is almost like \#1. However, when you go to balance the O, remember that the organic reactant has 1 O . We still need 22 O , but 1 is in the $\mathrm{C}_{7} \mathrm{H}_{16} \mathrm{O}$, so we only need 21 from $\mathrm{O}_{2}$.

$$
\mathrm{C}_{7} \mathrm{H}_{16} \mathrm{O}(\mathrm{l})+21 / 2 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 7 \mathrm{CO}_{2}(\mathrm{~g})+8 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

5. $\mathrm{C}_{6} \mathrm{H}_{14} \mathrm{O}_{2}(\mathrm{l})+17 / 2 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 6 \mathrm{CO}_{2}(\mathrm{~g})+7 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$
6. So what is the formula? It is $\mathrm{C}_{10} \mathrm{H}_{20}$. One way to find that is to write in all the H on the structure and then count everything. Another way is to count the C (there are 10), and then figure out the H . There might be 22 H for 10 C , but this structure is short 2 H , since it has one ring.

$$
\mathrm{C}_{10} \mathrm{H}_{20}(\mathrm{l})+15 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 10 \mathrm{CO}_{2}(\mathrm{~g})+10 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$
